(C)

1) $\varepsilon = 0.1$ learns fastest as it is the least random in the start

2) decaying ε because it starts extremly random and explores, then exploits this later when less random

3) because it still acts random when good policy is learned

(D)

1) different (Q-learning or Sarsa inspired policies)

2) Sarsa, accounts for exploration risk and is mor cautious

3) Sarsa => less risky

(E)

1) states near the goal are highest and vice versa. This matches my intuition.

2) Sarsa must use the actual next action to correctly update Q-value

3) Because the agent doesn't ~~learn~~ explore then

4) training is much longer as there are 64 states instead of 16.
